Claims

(currently amended) A method of producing heat energy, comprising the steps of:
 providing a container for receiving an electrolyte composition, a cathode and an anode;
 forming an electrolyte composition comprising D₂O and [an ionizable acid] sulfuric acid;
 placing a sufficient amount of the electrolyte composition in the container to at least
 partially cover a cathode made from a metal selected from the group consisting of [nonhydride
 forming metals] palladium, platinum and titanium and to at least partially cover an inert anode
 situated inside the container;

connecting the cathode and anode to a source of electricity; and applying a [voltage] <u>current density</u> across the cathode and anode <u>of at least 0.55A/cm²</u>.

Claim 2 (canceled).

- 3. (original) The method of claim 1 wherein the electrolyte during the application of voltage is held within a container and wherein said container bounds a space above the electrolyte, said space providing a region for the recombining of gases produced during the electrolysis.
- 4. (original) The method of claim 1 wherein a catalyst is provided within said region catalyzing the recombining of gases produced by the electrolysis.
- 5. (original) The method according to claim 1 wherein the cathode is made from palladium.
- 6. (original) The method according to claim 5 wherein the size of the cathode is about 1 cm².
- 7. (original) The method according to claim 1 wherein the cathode is made from titanium.

- 8. (original) The method according to claim 1 wherein the inert anode is a platinum anode.
- 9. (original) The method according to claim 1 wherein the electrolyte composition consists essentially of D₂O and about 15% sulfuric acid by volume.
- 10. (original) The method according to claim 9 wherein the cathode is made from palladium or titanium.
- 11. (original) A method of producing heat energy, comprising the steps of:
 providing a container for receiving an electrolyte composition, a cathode and an anode;
 forming an electrolyte composition comprising D₂O and sulfuric acid;
 placing a sufficient amount of the electrolyte composition in a container to at least
 partially cover a cathode made from a metal selected from the group consisting of nonhydride
 forming metals and to at least partially cover an inert anode situated inside the container;
 connecting said cathode and anode to a source of electricity; and
- 12. (original) A method of producing heat energy, comprising the steps of: providing a container for receiving an electrolyte composition, a cathode and an anode; forming an electrolyte composition consisting essentially of D₂O and 15% by volume sulfuric acid;

applying a voltage of about 3.5 volts across the cathode and anode.

placing a sufficient amount of the electrolyte composition in a container to at least partially cover a palladium or titanium cathode and an inert anode situated inside the container, wherein the container bounds a space above said electrolyte composition;

connecting said cathode and anode to a source of electricity;
applying a voltage across the cathode and anode; and
providing a catalyst within the space above the electrolyte composition to catalyze the
recombination of gases produced by the electrolyte.
